1 Introduction

This document describes PYMKEROS1_NODE (also spelled as `pymkerosl_node.py` in this document) v1.0, a ROS1 ¹ node from the `pymkeros` package for publishing 3D point cloud data provided by Magik Eye sensors. Currently, `pymkerosl_node.py` connects to Magik Eye devices that provide 3D data using the TCP/IP protocol. The `pymkerosl_node.py` codebase depends on the MKE API[mkeapi] Python client implementation `pymkeapi`. The following table lists the officially supported platforms for `pymkerosl_node.py`:

Ubuntu Version	ROS Distribution
Ubuntu 18.04 64bit	<i>ROS Melodic</i>
Ubuntu 20.04 64bit	<i>ROS Noetic</i>

Note

This document assumes that the reader has a working knowledge of ROS and the ROS package compilation procedure. Documentation or explanation of any of these topics is out of the scope of this document.

Upon launch, the `pymkerosl_node.py` registers a new node `pymkerosl_node_NAME`, where `NAME` is the node's unique identifier that depends on the command line parameters passed to the node executable. It also publishes two services: `pymkerosl_startpublish_NAME` and `pymkerosl_stoppublish_NAME`. Once the `pymkerosl_startpublish_NAME` service is invoked, the node connects to a Magik Eye sensor via TCP/IP network and starts publishing the sensor's 3D data stream under the `pymkerosl_node_pcd_NAME` topic. The topic is unpublished and the connection to the sensor closed upon invocation of the `pymkerosl_stoppublish_NAME` service.

2 Compilation

The `pymkerosl_node.py` ROS node compilation is based on the CMake build system and Catkin ². Let's suppose that the ROS distribution has been installed into the `${ROS_ROOT}` directory and the `pymkerosl_node.py` codebase resides in the `${PYMKEROS_ROOT}` ROS package of `${ROS1_WS}` ROS workspace. The following BASH commands will compile the `pymkerosl_node.py` into the `${ROS1_WS}/build/` directory:

```
$ mkdir "${ROS1_WS}/build"
$ cd "${ROS1_WS}/build"
$ source ${ROS_ROOT}/setup.bash
$ catkin_make --pkg pymkeros --source ..
```

This creates a `${ROS1_WS_DEVEL}` space in the `${ROS1_WS}/build` path. To test the `pymkerosl_node.py` compilation, execute the following commands:

```
$ source ${ROS1_WS_DEVEL}/setup.bash
$ rosrn pymkeros pymkerosl_node.py --help
```

¹ros.org

²<http://docs.ros.org/en/api/catkin/html>

2.1 Dependencies

The `pymkeros1_node.py` codebase depends on the MKE API Python client implementation called `pymkeapi`. The `pymkeapi` package is available as a pip-installable wheel archive. Alternatively, the root path of the `pymkeapi` package can be provided via the `PYTHONPATH` environment variable in the following manner:

```
$ export PYTHONPATH=$PYTHONPATH:/path/to/pymkeapi/
```

3 Execution

Once compiled, the `pymkeros1_node.py` can be invoked through the `pymkeros` package. The `help` parameter lists and describes the available command line parameters:

```
$ source ${ROS1_WS_DEVEL}/setup.bash
$ rosrun pymkeros pymkeros1_node.py --help
```

3.1 MKE Sensor Discovery

In order to connect to a Magik Eye sensor, the `pymkeros1_node.py` script needs to be provided with an IP address or a unit ID of the sensor in question. Since all Magik Eye TCP/IP-enabled sensors implement network discovery using the SSDP protocol, `pymkeros1_node.py` script provides the `discover` command line option that will list all MagikEye sensors connected to the local TCP/IP network. In the following example, the `pymkeros1_node.py` executable was able to discover two MagikEye sensors:

```
$ rosrun pymkeros pymkeros1_node.py --discover
MagikEyeOne-0242be55:192.168.0.100
MagikEyeOne-0242ac2a:192.168.4.101
```

The list specifies the unit ID's and respective IP addresses of the discovered sensors.

The `discover` parameter can be also used in combination with the `device` parameter to check the availability of a particular sensor. The value of the `device` parameter can be an IP address or a unit ID:

```
$ rosrun pymkeros pymkeros1_node.py --discover \
                                     --device MagikEyeOne-0242be55
$ echo $?
0
$ rosrun pymkeros pymkeros1_node.py --discover --device 192.168.0.100
$ echo $?
0
$ rosrun pymkeros pymkeros1_node.py --discover --device 192.168.0.102
$ echo $?
1
```

3.2 Launching

The `pymkeros1_node.py` node can be launched either by providing the connection information through the command line parameters or through a launch file.

Note

The `roscore` (rosmaster) process must already be running in order for the `roslaunch` or `roslaunch` commands to work.

3.2.1 Launching Through the Command Line

The node is launched when the launch and device parameters are provided:

```
$ roslaunch pymkeros pymkeros1_node.py --launch \  
    --device MagikEyeOne-0242be55  
[ INFO] [...]: Launching node: pymkeros1_node_MagikEyeOne_0242be55  
[ INFO] [...]: Starting service: ↩  
    pymkeros1_startpublish_MagikEyeOne_0242be55  
[ INFO] [...]: Starting service: ↩  
    pymkeros1_stoppublish_MagikEyeOne_0242be55
```

The above will launch a node called `pymkeros1_node_MagikEyeOne-0242be55` and start two services called `pymkeros1_startpublish_MagikEyeOne_0242be55` and `pymkeros1_stoppublish_MagikEyeOne_0242be55` respectively. Again, the device parameter can also contain the sensor's IP address. The sensor specific part of the node and services names can be overridden using the `alias` parameter:

```
$ roslaunch pymkeros pymkeros1_node.py --launch \  
    --device MagikEyeOne-0242be55  
    --alias s1  
[ INFO] [...]: Launching node: pymkeros1_node_s1  
[ INFO] [...]: Starting service: pymkeros1_startpublish_s1  
[ INFO] [...]: Starting service: pymkeros1_stoppublish_s1
```

Note

The node will *not* connect to the sensor upon launch, nor will it check the availability of the sensor. The connection will only be attempted upon invocation of the `pymkeros1_startpublish_NAME` service. For an immediate check of the sensor's availability, use the `discover` parameter.

3.2.2 Launching Through a Launch File

The launch file `${PYMKEROS_ROOT}/launch/pymkeros1.launch` can be used to launch the node with the default parameters described in `${PYMKEROS_ROOT}/config/pymkeros1_config.yaml`. The device parameter is a mandatory parameter of the launch file. The device parameter should be provided as an IP Address or a unit ID. The `alias` parameter is optional.

For example, the launch file `pymkeros1_config.yaml` can look as follows:

```
# Default configurations
device : "192.168.0.117"
# alias : "s1"
```

Launching the node using a launch file with the above parameters can be done using the `roslaunch` command:

```
$ roslaunch pymkeros pymkeros1.launch
```

Note

If `roslaunch` is used to launch the `pymkeros1_node.py` using the above method, then `roslaunch` should not be invoked to launch start and stop services or for other CLI parameters.

4 Services

Upon execution, the `pymkeros1_node.py` node publishes two services: `pymkeros1_startpublish_NAME` and `pymkeros1_stoppublish_NAME`.

Note

If `roslaunch` is used to launch the `pymkeros1_node.py`, then the services `pymkeros1_startpublish_NAME` and `pymkeros1_stoppublish_NAME` should be called using `rosservice call` command of ROS API.

4.1 Start Publishing

Once the `pymkeros1_startpublish_NAME` service is invoked, the node connects to a Magik Eye sensor via TCP/IP network and starts publishing the sensor's 3D data stream under the `pymkeros1_node_pcd_NAME` topic. If the sensor has been specified via its IP address, the node will try to connect to the sensor directly. In the case the sensor has been specified using its unit ID, the discovery procedure to recover its IP address will be performed. Once the connection is established, the `pymkeros1_node_pcd_NAME` topic is published.

The `pymkeros1_node.py` script provides a convenience parameter `start` to call the start service. The device can be specified via the `device` or `alias` options:

```
$ roslaunch pymkeros pymkeros1_node.py --start --alias s1
[ INFO] [...]: Calling service: pymkeros1_startpublish_s1
[ INFO] [...]: Service called successfully: pymkeros1_startpublish_s1
```

4.2 Stop Publishing

The `pymkeros1_node_pcd_NAME` topic is unpublished and the connection to the sensor closed upon invocation of the `pymkeros1_stoppublish_NAME` service.

The `pymkeros1_node.py` script provides a convenience parameter `stop` to call the stop service. The device can be specified via the `device` or `alias` options:

```
$ rosrun pymkeros pymkeros1_node.py --stop --alias s1  
[ INFO] [...]: Calling service: pymkeros1_stoppublish_s1  
[ INFO] [...]: Service called successfully: pymkeros1_stoppublish_s1
```

5 Accessing The Point Cloud Data

While publishing, the sensor data will be available on the topic called `pymkeros1_node_pcd_NAME`. The message format of the data published on this topic is `sensormsgs::PointCloud2`.
